Prompt

We catered 30% of city's energy demands in 2022!
Do you have an estimate for 2023?

Private Developer

We must plan energy consumption for a new institution in the city.
Can we get an estimate for the first year?

Private Players

Private Energy Supplier

Government

City Energy Authority

Jeez! Do we have the answers?

We've been capturing all this DATA! It's time we USE IT!
Can we use MACHINE LEARNING?

City Planner

Washington, DC

Data availability

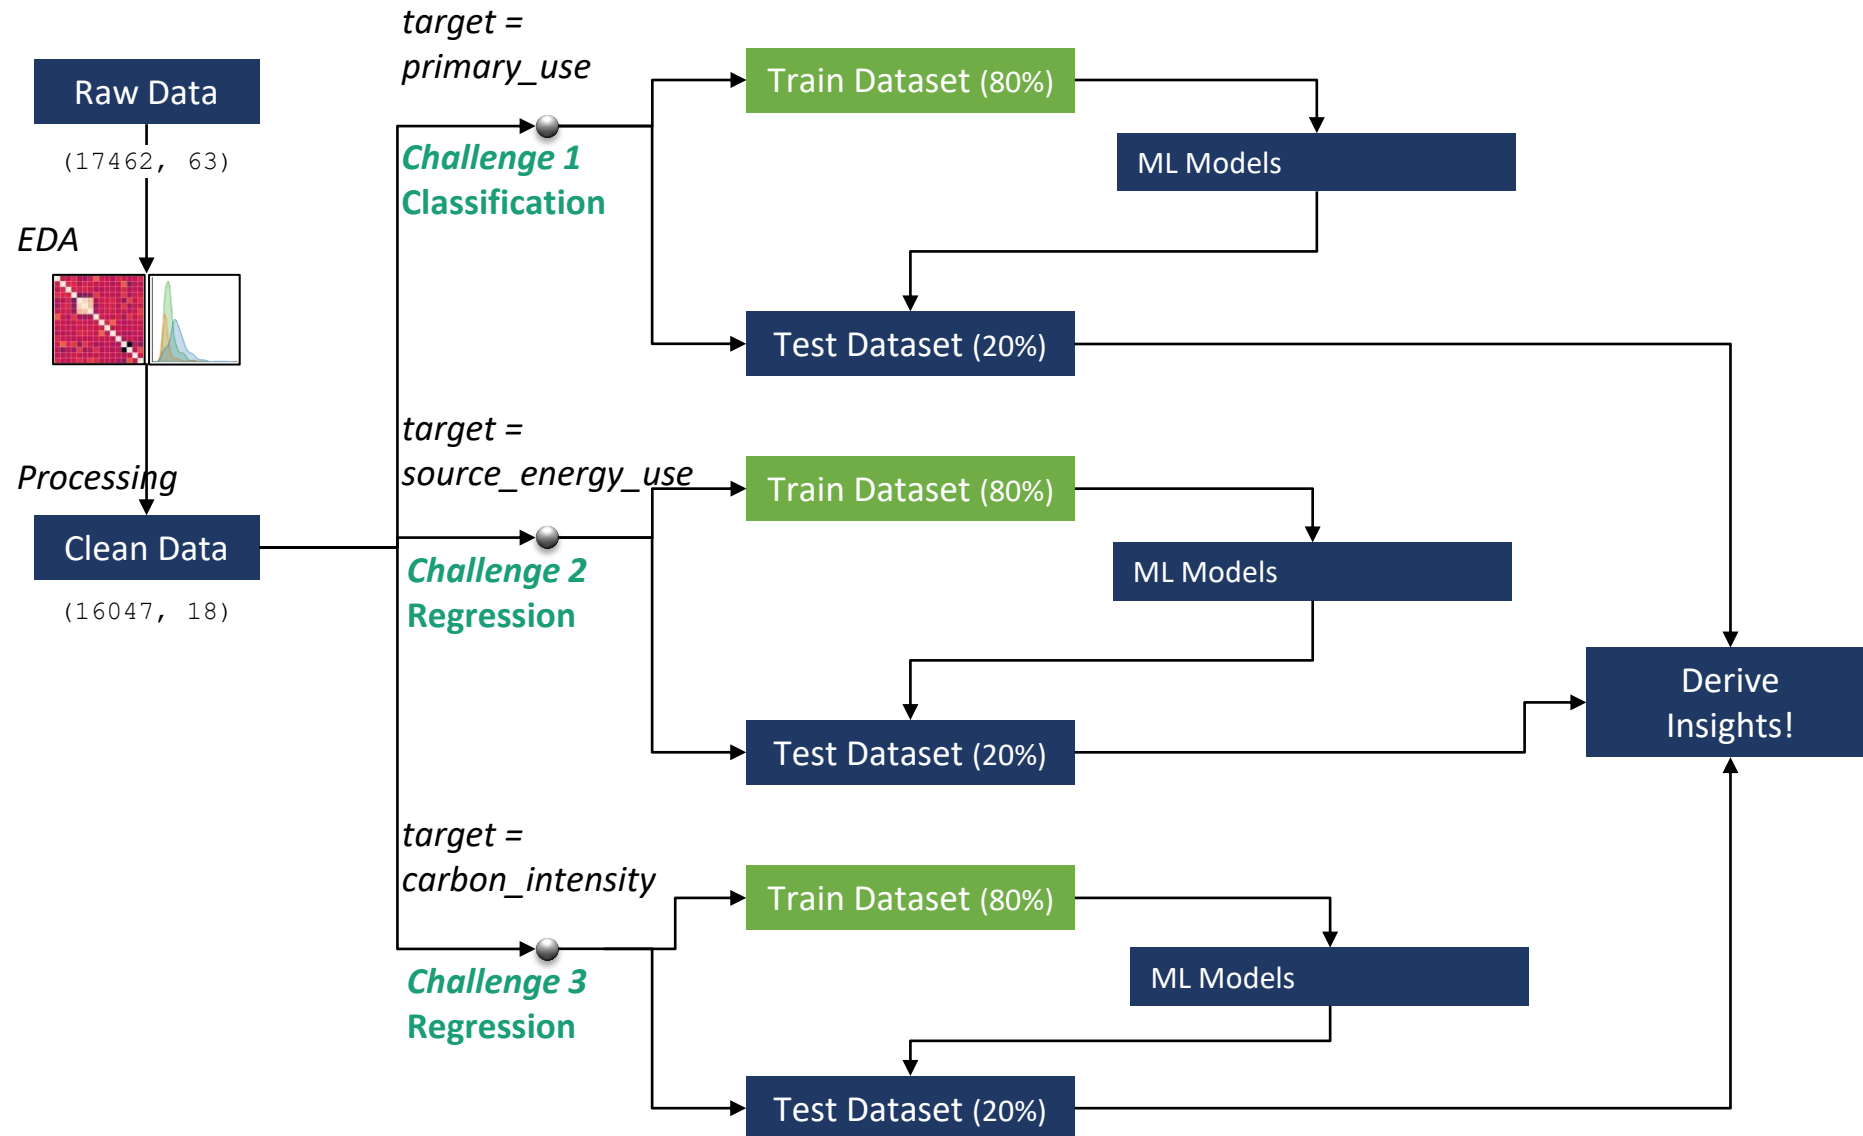

The three challenges

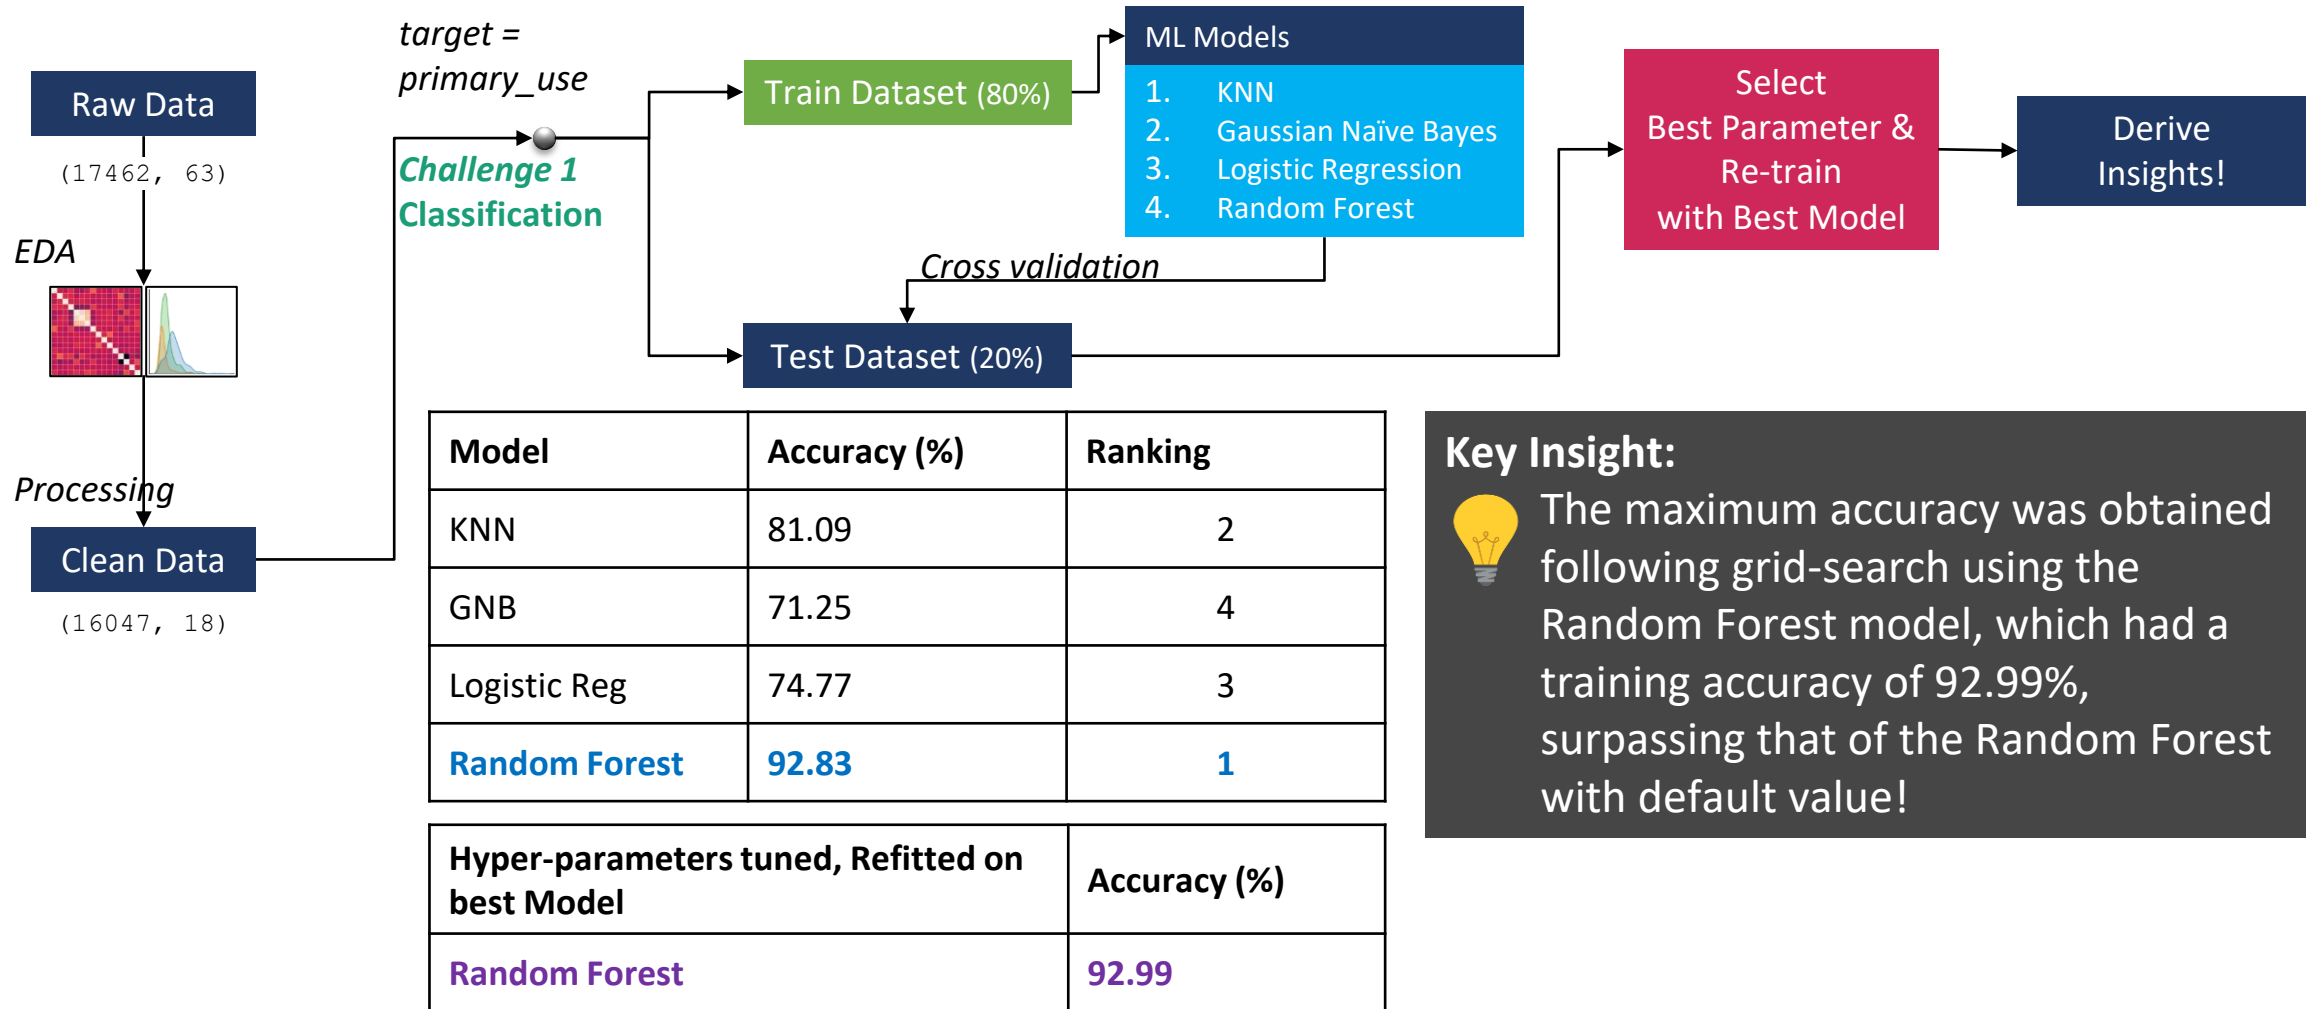

1. Predict primary use of the building
 - 'Residential', 'Commercial', or 'Institutional'
2. Forecasting the building's EUI to describe the building energy use
 - Better prescribe predicted energy consumption.
 - Help the city authorities to plan the city's energy distribution for future scenarios.
3. Predict Carbon Intensity
 - Based on predicted primary use and EUI along with other features

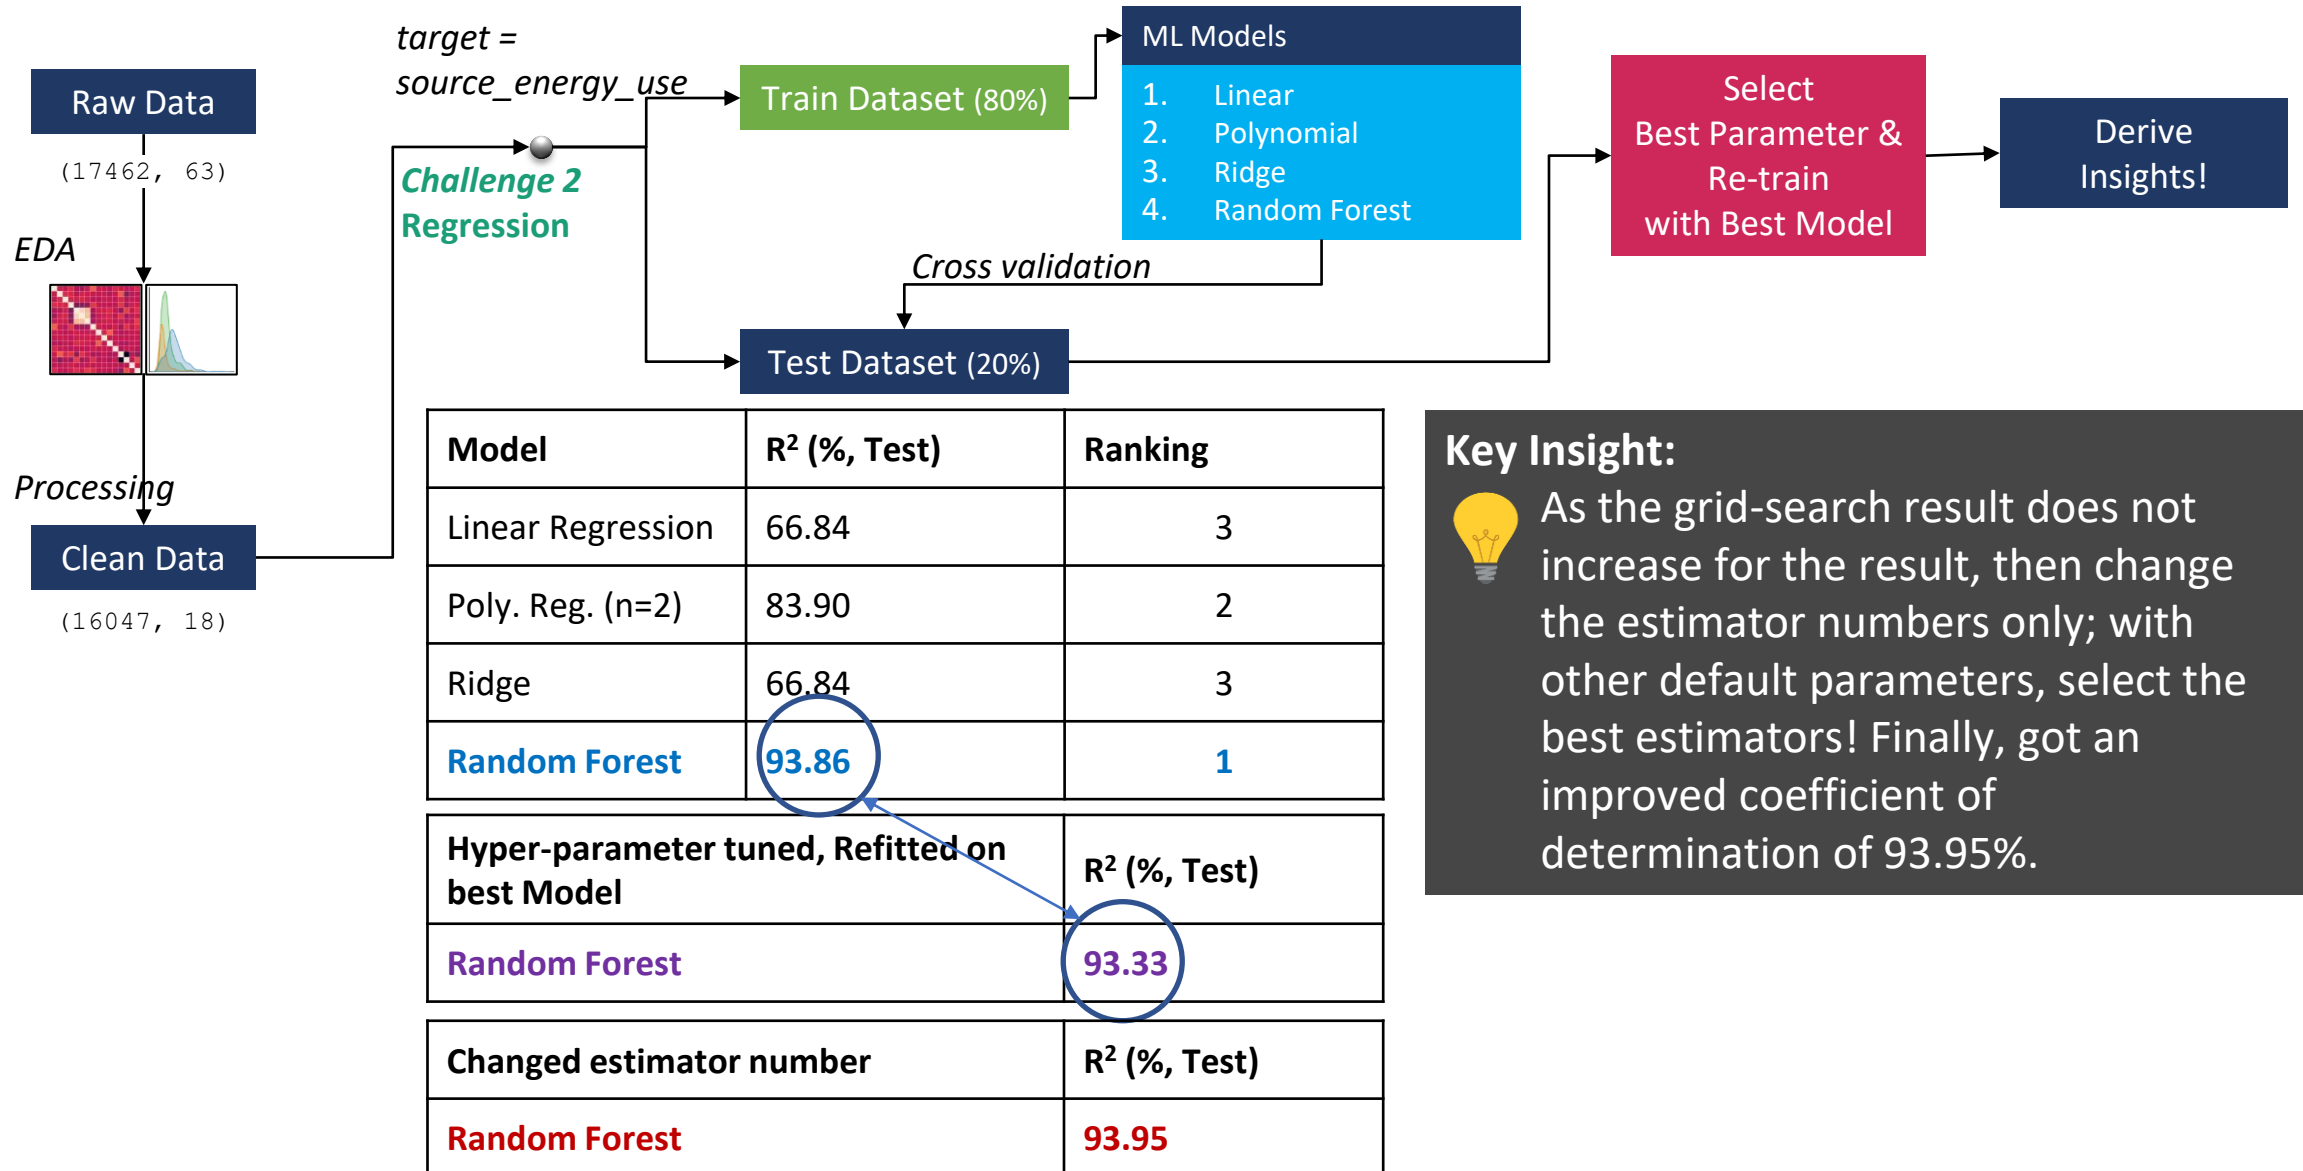

Data mining process adopted:

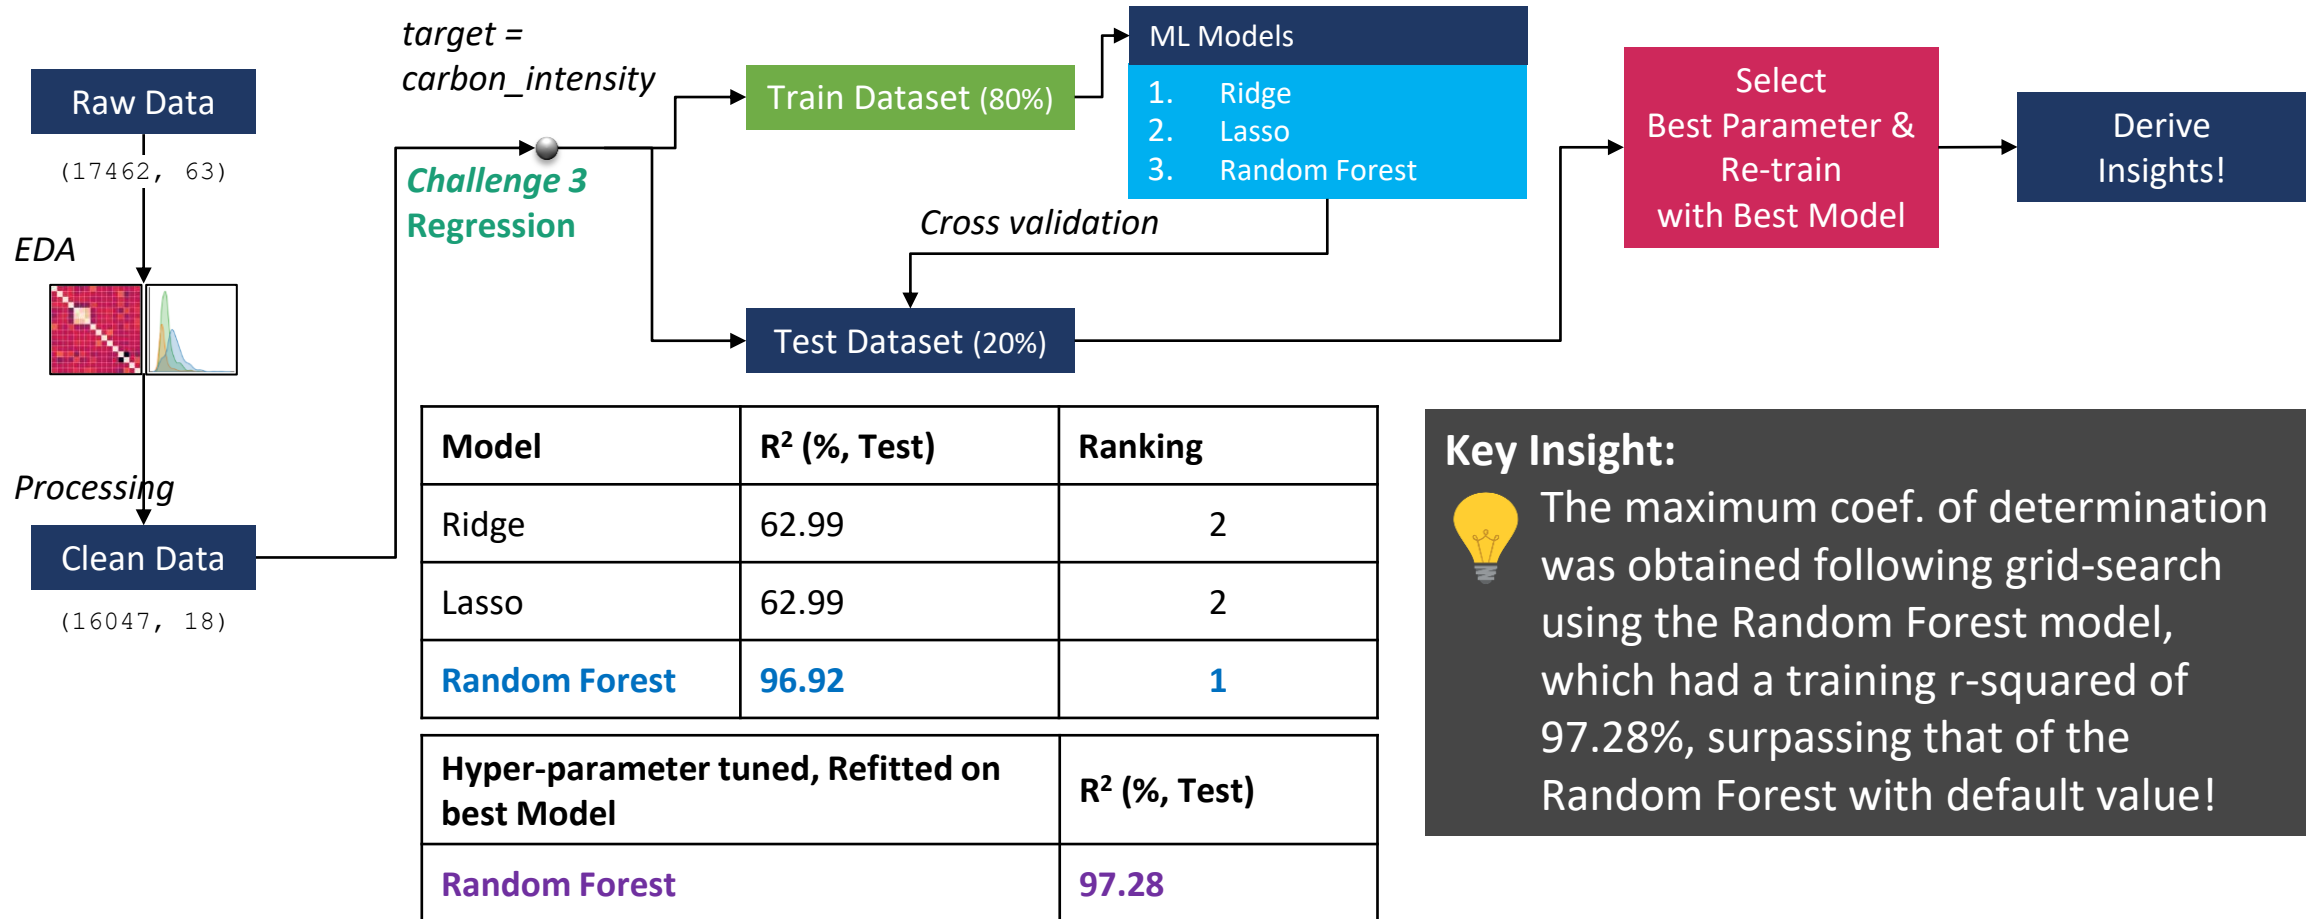

Challenge 1: Predict 'primary use'

Challenge 2: Predict 'energy use intensity'

Challenge 3: Predict 'carbon intensity'

Conclusions

- Random Forest classification predict building primary use type efficiently.
- Random Forest Regression performs the best compared to Linear, Ridge and Polynomial models to predict the source energy use intensity.
- Random Forest Regression with Grid-search can achieve the best result compared to Lasso, Ridge models to predict carbon intensity

Future work

- 'Repeatability' in other cities!
- Demographic and meteorological data can also be used in this study.
